

1 Description

2
3 Method for the generation of electrical pulses

4
5 The invention relates to a method for the generation of
6 electrical pulses, in which input signals from a reference
7 source are fed into calculation means, under program control
8 using entered parameters the calculation means calculate
9 control values dependent on the input signals for
10 controlling a pulse generation circuit, and the pulse
11 generation circuit generates a temporal sequence of
12 electrical voltage levels at at least one output as a
13 function of the control values.

14
15 Problems occur with regard to generating electrical pulses
16 in a large number of technical systems. The situation is
17 known from motor vehicles, for example, where a rotating
18 mechanical system, namely a component of the motor vehicle
19 engine, serves as a reference source which uses cyclically
20 repeated signals as a reference for the generation of
21 electrical control pulses that are in turn used for
22 controlling further electromechanical devices such as
23 injection valves, injectors etc. In accordance with the
24 terminology of the preamble of Claim 1, three levels can be
25 functionally differentiated in this situation. The actual
26 electrical pulses are generated as a temporal sequence of
27 different electrical voltage levels at the output of an
28 actual pulse generation circuit. This can for example
29 comprise an arrangement of transistors and other electronic
30 components which are controlled in a suitable manner by the
31 input of control values. The control values are the result
32 of a calculation by calculation means, a microprocessor for
33 example, which receive on the one hand reference signals as
34 their input data from a cyclical reference source and on the
35 other hand use certain computing rules and parameters in
36 order to define the pulses to be generated, with the result

1 that a conversion of this information into control values
2 suitable for the special pulse generation circuit can take
3 place. It should be noted that the division into three
4 functional levels is only used for purposes of explanation
5 within the scope of the present description, and that with
6 regard to the concrete, technical implementation the
7 calculation means and pulse generation circuit can for
8 example be designed as a combined device however, as an
9 interface card or similar for example.

10
11 In the case of generic devices according to the prior art,
12 the pulses are always defined in a fixed manner, in other
13 words by means of specified parameters, and the definitions
14 of different pulses are differentiated solely in the sizes
15 of the definition parameters. A pulse is thus frequently
16 defined by its beginning and its duration, whereby the
17 beginning is described as an angle and the duration as a
18 time. Another known possible means of definition consists in
19 describing the pulse by means of its end and its duration,
20 whereby the end is described as an angle and the duration as
21 a time. Finally, a method is known for describing a single
22 pulse by its beginning and its end, whereby both parameters
23 take the form of an angle. The type of definition
24 specifically chosen depends on the control values which are
25 required in order to control the pulse generation circuit.

26
27 This arrangement conceals a significant disadvantage. The
28 definitions of different pulses generally originate from
29 mathematical calculations representing physical events. If,
30 for example, the physical events change during the operation
31 of the overall system it may be the case that changed pulses
32 need to be calculated and generated, whereby the
33 mathematical description of the changed physical events
34 would be provided most advantageously by means of an adapted
35 pulse definition with adapted parameters. Instead, in the
36 case of known systems it is merely possible to change the

1 sizes of the defined parameters in such a way that a pulse
2 definition must be used which does not result naturally from
3 the mathematical modeling of the underlying physical events.
4 This results in more complex programming and longer
5 calculation times.

6
7 An object of the present invention is to develop a generic
8 method such that the aforementioned problems associated with
9 the prior art are overcome, in particular to set down a
10 method which enables greater flexibility in the definition
11 of the pulses to be generated. This object is achieved in
12 conjunction with the features of the preamble of Claim 1 by
13 the fact that the entered parameters in each case comprise a
14 pair of values, of which one value represents a size for the
15 entered parameter and another value represents a type for
16 the entered parameter, and the processing of the size for
17 the parameter in the calculation means takes place as a
18 function of the type of the entered parameter.

19
20 According to the invention, the parameters for the
21 definition of the pulses are entered as a pair of values, of
22 which one value, as previously, represents the size for the
23 parameter. An additional value specifies the type of the
24 parameter, in other words whether it is for example an
25 angle, a time or some other type of parameter. The
26 calculation means are able to use the additional value to
27 correctly categorize and interpret the size value for the
28 parameter and to execute the suitable subroutines in order
29 to calculate the control values for controlling the actual
30 pulse generation circuit.

31
32 Provision is advantageously made whereby each pulse to be
33 output by the pulse generation circuit is defined by means
34 of two parameters. This is the number of parameters which is
35 required and sufficient for defining a pulse. As mentioned
36 previously, the calculation means are able to use the

1 additional values for each individual parameter to correctly
2 categorize the entered parameters. They are preferably also
3 able to choose and execute the suitable routines for
4 calculating the control values for the pulse generation
5 circuit from the combination of the types of the parameter
6 pair entered for defining a pulse.

7
8 The parameters used for defining a pulse can represent time
9 and/or angle sizes. In this situation, a pulse can be
10 defined for example by an angle size and a time size. It is
11 thus possible for example to specify the position of the
12 pulse on the basis of the angle of the beginning of the
13 pulse relative to a reference angle and also the pulse
14 duration as a time. It is similarly possible to specify the
15 pulse position as the angle of the end of the pulse relative
16 to a reference angle and the pulse duration as a (negative)
17 time. The reference angle can be an absolute reference
18 angle, for example a top dead center in an engine, serving
19 as the reference source. On the other hand, a characteristic
20 value for an adjacent pulse can also serve as the reference
21 angle. With regard to a different approach, which can also
22 result in a pulse definition by means of an angle size and a
23 time size, it is not a position and a pulse duration but two
24 positions, namely that of a falling edge and that of a
25 rising edge, which are determined. Without restricting the
26 universality, it is assumed in the following to be a case of
27 negative pulses whose falling edge precedes the rising edge
28 in time. The invention can naturally also be applied to
29 positive pulses having a reversed sequence of falling and
30 rising edges.

31
32 With regard to another preferred embodiment of the method
33 according to the invention, provision is made whereby two
34 angle sizes are used for the definition of a pulse.
35 Provision can be made here for example to specify the
36 position of the beginning of the pulse as an angle relative

1 to a reference angle and the pulse duration as a difference
2 angle. It is similarly possible to specify the position of
3 the end of the pulse as an angle relative to a reference
4 angle and the pulse duration as a (negative) difference
5 angle. Instead of the position and pulse duration, with this
6 embodiment it is also possible to describe a pulse by
7 specifying its falling and rising edges which are then
8 defined in each case as an angle relative to a reference
9 angle. It also holds true here that the reference angle can
10 be both an absolute reference angle and also an angle
11 relating to an adjacent pulse.

12
13 Finally, as provided in the case of a further preferred
14 embodiment of the method according to the invention, it is
15 possible for two time sizes to be used for the definition of
16 a pulse. In this case, it is possible for example to specify
17 the position of the beginning of the pulse as a first time
18 and the pulse duration as a second time. According to the
19 second methodology, the two edges of a pulse can also each
20 be specified by means of a time value. In this situation,
21 the time specification can in each case be made relative to
22 a temporally preceding point in time or relative to a
23 temporally following point in time, which results in the
24 specification of positive and negative times respectively.
25 This makes it possible to define the pulses relative to
26 absolute reference points in time, relative to adjacent
27 preceding pulses or relative to adjacent following pulses.

28
29 As a result of the diversity of options provided according
30 to the invention for the definition of the pulses to be
31 generated the overall system can be implemented in a
32 particularly flexible manner and the pulse definition can
33 take place in each case in such manner as results most
34 favorably from the mathematical modeling of the underlying
35 physical problem or of the physical circumstances.

36

1 In a preferred embodiment of the method according to the
2 invention, provision is made whereby the definition of a
3 pulse is different during different cycles of the method. As
4 mentioned previously, a change in the pulse definition is
5 then frequently required when physical circumstances
6 affecting the overall system change. The changes are often
7 of a type which necessitates changed modeling of the
8 physical circumstances. This can in turn make it appear
9 advantageous to change the manner of definition for the
10 pulses to be generated. The present invention makes it
11 possible to always use the optimized manner of definition
12 instead, as in the prior art, of having to keep to a fixed
13 manner of definition and merely being able to change the
14 parameter sizes.

15

16 The system referred to above as "overall system" will often
17 be an electromechanical system whose current physical
18 conditions, dependent for example on a special operating
19 state, predetermine the optimum manner of definition for the
20 parameters. In this situation, in particular the reference
21 source will particularly frequently comprise a rotating
22 mechanical system such as rotating components of the engine
23 of a motor vehicle, for example.

24

25 It should be noted that, although within the scope of this
26 description reference is always made to individual pulses
27 and their definition, it is not imperative for the present
28 invention that each individual pulse generated is calculated
29 individually by the computing unit on the basis of separate
30 input values. It is naturally also possible to perform the
31 re-calculation simply in the event of definition or size
32 changes.

33

34 Further details of the present invention will emerge from
35 the detailed description which follows with reference to the
36 drawings. In the drawings:

Figure 1 shows a tree diagram providing an explanation of the pulse definition according to the invention,

Figure 2 shows a functional block diagram illustrating the method according to the invention,

Figure 3 shows four examples of a possible pulse definition,

Figure 4 shows four further examples of a possible pulse definition,

Figure 5 shows four further examples of a possible pulse definition, and

Figure 6 shows an example of the definition of a pulse sequence.

Figure 1 schematically illustrates the structure of a pulse definition according to the invention. Each pulse 15 is preferably defined by means of two parameters which for their part are each entered as a pair of values into the calculation means. Each pair of values comprises a value for the actual parameter size and an additional value for determining the parameter type (for example angle, time etc.). It should be noted that the term input should be understood in a broad sense within the scope of this description and includes the incorporation of values from any suitable type of interfaces (for example software interface, hardware interface, own calculation etc.).

Figure 2 shows a functional block diagram of the method according to the invention. A calculation means block 10 receives input values from a reference source 11 on the one hand. Any harmonically oscillating system is suitable for

1 this purpose, rotating systems in particular, such as the
2 engine of a motor vehicle for example, whereby merely
3 characteristic values, denoting the respective top dead
4 centers for example, need to be transferred to the
5 calculation means 10. On the other hand, the calculation
6 means 10 receive pulse definitions constructed by a
7 parameter source 12 in accordance with Figure 1. Different
8 combinations of angles (α , β) and/or time values (τ , t_1 , t_2)
9 symbolize possible parameter combinations by way of example.

10
11 Using the reference values from the reference source 11, the
12 calculation means calculate from the pulse definitions
13 control values which are used for controlling the actual
14 pulse generation circuit 13. In response to the input of the
15 control values the pulse generation circuit 13 makes
16 available at its outputs 14 a sequence of different
17 electrical voltage levels which represent the desired pulse
18 sequence 15. As mentioned previously, the functional
19 division as illustrated in Figure 2 is undertaken only in
20 order to provide a better explanation of the present
21 invention. Systems actually implemented can collectively
22 incorporate a plurality of the units shown or in a different
23 grouping.

24
25 Figure 3 illustrates four possible options for pulse
26 definition by means of pulse position and pulse duration,
27 whereby at least one angle parameter is used in each case.
28 Figure 3a shows the pulse definition given by specifying the
29 position of the beginning of the pulse as angle α relative
30 to a reference angle and the pulse duration given by
31 specifying a difference angle β relative to the position
32 angle α .

33
34 Figure 3b shows a pulse definition given by specifying the
35 end of the pulse as angle γ relative to a reference angle

1 and by specifying the pulse duration as a negative
2 difference angle $-\beta$ relative to the position angle γ .

3
4 Like Figure 3a, Figure 3c shows a pulse definition given by
5 specifying the beginning of the pulse as angle α relative to
6 a reference angle. In this case, however, the pulse duration
7 is specified as a time τ .

8
9 Like Figure 3b, Figure 3d shows a pulse definition given by
10 specifying the end of the pulse as angle γ relative to a
11 reference angle. In this case, however, the pulse duration
12 is specified as a negative time $-\tau$.

13
14 Figure 4 shows possible options for pulse definition of
15 pulse n by using two time parameters. In this situation,
16 Figure 4a shows the pulse definition given by specifying the
17 beginning of the pulse as time τ_1 relative to a reference
18 time, in particular to the end of a preceding pulse $n-1$. The
19 pulse duration is specified as time τ_2 .

20
21 Figure 4b shows a pulse definition given by specifying the
22 end of the pulse as time τ_3 relative to a reference point in
23 time, in particular to the end of the preceding pulse $n-1$.
24 The pulse duration is specified here as a negative time $-\tau_2$.

25
26 Figure 4c shows a pulse definition given by specifying the
27 beginning of the pulse as a negative time $-\tau_4$ relative to a
28 temporally following reference point in time, here in
29 particular relative to the beginning of the following pulse
30 $n+1$. The pulse duration is specified as time τ_2 .

31
32 Figure 4d shows a pulse definition given by specifying the
33 end of the pulse as a negative time $-\tau_5$ relative to a
34 temporally following reference point in time, here in
35 particular relative to the beginning of the following pulse

1 n+1. The pulse duration is specified here as a negative time
2 $-\tau_2$.

3
4 Figure 5 shows examples of pulse definition in which it is
5 not the pulse position and pulse duration that are specified
6 but the locations of the falling edge and the rising edge.
7 With regard to the negative pulses shown in this example,
8 the falling edge precedes the rising edge in time. The
9 person skilled in the art will however experience no
10 difficulties in transferring to positive pulses, in which
11 situation the rising edge precedes the falling edge in time.
12 Figure 5a shows a pulse definition whereby the falling and
13 rising edges are each defined as angles α and β respectively
14 relative to a reference angle.

15
16 In the example shown in Figure 5b the location of the
17 falling edge is likewise defined as angle α relative to a
18 reference angle, whereas the location of the rising edge is
19 described as a time t relative to the falling edge.

20
21 Figure 5c shows the determination of the rising edge as
22 angle β relative to a reference angle and the determination
23 of the falling edge as time specification t relative to the
24 rising edge.

25
26 Figure 5d finally shows the determination of the falling
27 edge as time specification t_1 relative to a temporally
28 preceding event, here in particular relative to the rising
29 edge of the temporally preceding pulse. The rising edge is
30 described in this example as time specification t_2 relative
31 to the falling edge.

32
33 Figure 6 finally shows an example of a pulse sequence in
34 which the individual pulses are defined in different ways.
35 Pulse $n-1$ is defined by the specification of an angle α for
36 its falling edge and also by a further angle β for its

1 rising edge. In this situation, both angles α , β refer to a
2 reference value which is not shown. The pulse n-1
3 corresponds to an example according to Figure 5a. The
4 following pulse n is defined by a time specification t_1 for
5 its falling edge, whereby this time specification is
6 determined relative to the rising edge of the preceding
7 pulse n-1. The rising edge of pulse n is defined as time t_2
8 relative to the falling edge of pulse n. This corresponds to
9 a pulse definition according to Figure 5d. Finally, the
10 temporally following pulse n+1 is defined in the same way as
11 pulse n, whereby however the size for the time parameter t'_1
12 changes for determining the falling edge whereas the size
13 for the time parameter t_2 remains unchanged for determining
14 the rising edge.

15

16 The embodiments of the present invention described and shown
17 in the figures naturally simply represent particularly
18 favorable and advantageous exemplary embodiments which serve
19 simply to illustrate the invention and are not intended to
20 restrict its scope in any way. In particular, instead of or
21 in addition to the aforementioned angle and time
22 specifications it is possible to use other physical or
23 mathematical sizes in order to define the pulses.

24

25 The features of the invention disclosed in the above
26 description, in the drawings and also in the claims can be
27 important both individually and also in any desired
28 combination for the realization of the invention.
